

# PERVERSE SHEAVES ON SEMI-ABELIAN VARIETIES – A SURVEY OF PROPERTIES AND APPLICATIONS

YONGQIANG LIU, LAURENTIU MAXIM, AND BOTONG WANG

*Dedicated to the memory of Prof. Ștefan Papadima*

ABSTRACT. We survey recent developments in the study of perverse sheaves on semi-abelian varieties. As concrete applications, we discuss various restrictions on the homotopy type of complex algebraic manifolds (expressed in terms of their cohomology jump loci), homological duality properties of complex algebraic manifolds, as well as new topological characterizations of semi-abelian varieties.

## 1. INTRODUCTION

In recent years, perverse sheaves have become indispensable tools for studying complex algebraic varieties. They have seen important applications in fields like geometry and topology (e.g., the decomposition theorem [BBD82] and the topology of complex

*Key words and phrases.* semi-abelian variety, perverse sheaf, Mellin transformation, cohomology jump loci, Albanese map, generic vanishing, abelian duality space.

algebraic maps), representation theory (e.g., proof of the Kazhdan-Lusztig conjecture, proof of the geometrization of the Satake isomorphism, proof of the fundamental lemma in the Langlands program, etc.), or geometric combinatorics (e.g., Stanley’s proof of McMullen’s conjecture [Sta80], Huh-Wang’s resolution of the Dowling-Wilson “top-heavy conjecture” [HW17], etc.); see [CM09] for a nice survey, and also [M18, Sections 9.3 and 9.4]. Furthermore, perverse sheaves are the backbone of M. Saito’s mixed Hodge module theory [Sai88, Sai90], a far-reaching generalization of Hodge theory.

However, despite their fundamental importance, perverse sheaves remain rather mysterious objects. In his 1983 ICM address, MacPherson [Mac84] stated the following:

*“The category of perverse sheaves is important because of its applications. It would be interesting to understand its structure more directly.”*

Alternative descriptions of perverse sheaves have since been given in various contexts, e.g., in [MV86] (in terms of zig-zags), or in [GMV96] (using quivers). Perverse sheaves on complex affine tori have been studied by Gabber-Loeser [GL96] via the Mellin transformation. Perverse sheaves on abelian varieties have been recently described by Schnell in [Sch15] via properties of their cohomology jump loci. The references [GL96, Sch15] are the departure point for much of the work in [LMW18a, LMW18b], which is surveyed here, where a complete (global) characterization of  $\mathbb{C}$ -perverse sheaves on semi-abelian varieties is given in terms of their cohomology jump loci. It is also shown in [LMW18b] (and extending our earlier results from [LMW18a]) that perverse sheaves on semi-abelian varieties satisfy a set of properties, collectively termed the *propagation package*. Besides providing new obstructions on the homotopy type of smooth complex quasi-projective varieties (via their cohomology jump loci), the propagation package also has other important topological applications, such as finiteness properties of Alexander-type invariants, generic vanishing of Novikov homology, or for the study of homological duality properties of complex algebraic varieties (see also [LMW17a, LMW17b]).

The purpose of this survey is to provide a gentle introduction to these concepts and results, with an emphasis on geometric examples, applications and open questions.

## 2. PRELIMINARIES

Our study of perverse sheaves on semi-abelian varieties is partly motivated by the problem of understanding possible homotopy types of complex algebraic varieties. In this section, we collect the main definitions and technical tools needed to formulate our results from [LMW18a] and [LMW18b].

**2.1. Cohomology jump loci.** Let  $X$  be a smooth connected complex quasi-projective variety with positive first Betti number, i.e.,  $b_1(X) > 0$ . The *character variety*  $\text{Char}(X)$  of  $X$  is the identity component of the moduli space of rank-one  $\mathbb{C}$ -local systems on  $X$ , i.e.,

$$\text{Char}(X) := \text{Hom}(H_1(X, \mathbb{Z})/\text{Torsion}, \mathbb{C}^*) \cong (\mathbb{C}^*)^{b_1(X)}.$$

**Definition 2.1.** The  $i$ -th cohomology jump locus of  $X$  is defined as:

$$\mathcal{V}^i(X) = \{\rho \in \text{Char}(X) \mid H^i(X, L_\rho) \neq 0\},$$

where  $L_\rho$  is the unique rank-one  $\mathbb{C}$ -local system on  $X$  associated to the representation  $\rho \in \text{Char}(X)$ .

The jump loci  $\mathcal{V}^i(X)$  are closed subvarieties of  $\text{Char}(X)$  and homotopy invariants of  $X$ . They provide a unifying framework for the study of a host of questions concerning homotopy types of complex algebraic varieties. In particular, they can be used to tackle Serre's problem concerning groups which can be realized as fundamental groups of smooth complex quasi-projective varieties.

**Remark 2.2.** The jump loci  $\mathcal{V}^i(X)$  can in fact be defined for an arbitrary finite CW complex  $X$ . We list a few properties related to the jump loci, which are useful in computations:

- (a) If  $X$  is a finite connected CW complex, then  $\mathcal{V}^0(X) = \{\mathbb{C}_X\}$  consists of just one point, the trivial rank-one local system.
- (b) If  $X$  is a closed oriented manifold of real dimension  $n$ , then Poincaré duality yields that

$$H^i(X, L_\rho)^\vee \cong H^{n-i}(X, L_{\rho^{-1}})$$

for all  $i$ .

- (c) For all  $\rho \in \text{Char}(X)$  with associated rank-one local system  $L_\rho$ , one has  $\chi(X) = \chi(X, L_\rho)$ , with  $\chi$  denoting the corresponding Euler characteristic.

We include here the following elementary examples.

**Example 2.3.** If  $X = S^1$ , Poincaré duality yields that  $\mathcal{V}^i(X) = \begin{cases} \{\mathbb{C}_X\}, & \text{if } i = 0, 1 \\ \emptyset, & \text{otherwise.} \end{cases}$

If  $X = (S^1)^n$ , the Künneth Theorem yields that  $\mathcal{V}^i(X) = \begin{cases} \{\mathbb{C}_X\}, & \text{if } 0 \leq i \leq n \\ \emptyset, & \text{otherwise.} \end{cases}$

**Example 2.4.** Let  $X = \Sigma_g$  be a smooth complex projective curve of genus  $g \geq 2$ . Then

$\chi(X) = 2 - 2g \neq 0$ , and Poincaré duality yields that  $\mathcal{V}^i(X) = \begin{cases} \{\mathbb{C}_X\}, & \text{if } i = 0, 2, \\ \text{Char}(X), & \text{if } i = 1, \\ \emptyset, & \text{otherwise.} \end{cases}$

**2.2. Semi-abelian varieties.** As will be discussed below, the classical Albanese map construction allows us to interpret the cohomology jump loci of a smooth connected complex quasi-projective variety as cohomology jump loci of certain constructible complexes of sheaves (or even of perverse sheaves, if the Albanese map is proper) on a semi-abelian variety.

Recall that an *abelian variety* of dimension  $g$  is a compact complex torus  $\mathbb{C}^g/\mathbb{Z}^{2g}$ , which is also a complex projective variety. A *semi-abelian variety*  $G$  is an abelian complex algebraic group, which is an extension

$$1 \rightarrow T \rightarrow G \rightarrow A \rightarrow 1,$$

where  $A$  is an abelian variety and  $T$  is a complex affine torus.

(Semi-)abelian varieties are naturally associated to smooth (quasi-)projective varieties via the *Albanese map* construction, see [Lit76]. Specifically, if  $X$  is a smooth complex quasi-projective variety, the *Albanese map* of  $X$  is a morphism

$$\text{alb} : X \rightarrow \text{Alb}(X)$$

from  $X$  to a semi-abelian variety  $\text{Alb}(X)$  such that for any morphism  $f : X \rightarrow G$  to a semi-abelian variety  $G$ , there exists a unique morphism  $g : \text{Alb}(X) \rightarrow G$  such that the following diagram commutes:

$$\begin{array}{ccc} X & \xrightarrow{\text{alb}} & \text{Alb}(X) \\ & \searrow f & \downarrow g \\ & & G \end{array}$$

Here,  $\text{Alb}(X)$  is called the *Albanese variety* associated to  $X$ .

An important property of the Albanese map (cf. [Lit76]) is that it induces an isomorphism on the torsion-free part of the first integral homology groups, i.e.,

$$(1) \quad H_1(X, \mathbb{Z})/\text{Torsion} \xrightarrow{\cong} H_1(\text{Alb}(X), \mathbb{Z}).$$

In particular, (1) yields the identification:

$$(2) \quad \text{Char}(X) \cong \text{Char}(\text{Alb}(X)),$$

and the equality of Betti numbers  $b_1(X) = b_1(\text{Alb}(X))$ . Moreover, the dimension of the abelian part of  $\text{Alb}(X)$  is  $\dim_{\mathbb{C}} H^{1,0}$  and the dimension of the affine torus part of  $\text{Alb}(X)$  is  $\dim_{\mathbb{C}} H^{1,1}$ , where  $H^{1,0}$  and  $H^{1,1}$  denote the weight  $(1, 0)$  and, resp., weight  $(1, 1)$  parts of the mixed Hodge structure on  $H^1(X)$ . Note also that if  $X$  is smooth and projective, then  $H^1(X)$  carries a pure Hodge structure of weight 1 and  $\text{Alb}(X)$  is an abelian variety. On the other hand, if  $X$  is a smooth quasi-projective variety so that the mixed Hodge structure on  $H^1(X)$  is of type  $(1, 1)$ , then  $\text{Alb}(X)$  is a complex affine torus. Examples of such smooth varieties with first cohomology group of type  $(1, 1)$  include complements of essential hyperplane arrangements and complements of toric hyperplane arrangements.

**2.3. Constructible complexes and perverse sheaves.** *Constructible sheaves* are the algebraic counterpart of the decomposition of a variety  $X$  into manifolds pieces. In more detail, a sheaf  $\mathcal{F}$  of  $\mathbb{C}$ -vector spaces on  $X$  is *constructible* if there exists a finite stratification  $X = \sqcup_{\lambda} S_{\lambda}$  of  $X$  into locally closed smooth subvarieties (called *strata*), such that the restriction of  $\mathcal{F}$  to each stratum  $S_{\lambda}$  is a  $\mathbb{C}$ -local system of finite rank. A complex  $\mathcal{F}^{\bullet}$  of sheaves of  $\mathbb{C}$ -vector spaces on  $X$  is called constructible if its cohomology sheaves  $\mathcal{H}^i(\mathcal{F}^{\bullet})$  are all constructible. Denote by  $D_c^b(X; \mathbb{C})$  the bounded derived category of constructible complexes on  $X$ . Roughly speaking, two bounded constructible complexes with a map between them are identified in  $D_c^b(X; \mathbb{C})$  if the complexes contain the same cohomological information. For  $\mathcal{F}^{\bullet} \in D_c^b(X; \mathbb{C})$ , only finitely many of its cohomology

sheaves are nonzero and, for every  $i$ , the set  $\text{supp } \mathcal{H}^i(\mathcal{F}^\bullet)$ , i.e., the closure of the set of points at which the stalk of  $\mathcal{H}^i(\mathcal{F}^\bullet)$  is nonzero, is an algebraic subvariety of  $X$ . There is also a general form of duality for complexes (called *Verdier duality*) generalizing classical Poincaré duality.

*Perverse sheaves* are an important class of constructible complexes, introduced in [BBD82] as a formalization of the celebrated Riemann-Hilbert correspondence of Kashiwara [Ka80, Ka84] and Mebkhout [Me80, Me84], which relates the topology of algebraic varieties (intersection homology) and the algebraic theory of differential equations (microlocal calculus and holonomic  $D$ -modules). A perverse sheaf on  $X$  is a bounded constructible complex  $\mathcal{P} \in D_c^b(X; \mathbb{C})$  such that the following vanishing property holds for  $\mathcal{F}^\bullet = \mathcal{P}$  and for its Verdier dual  $\mathcal{P}^\vee$ :

$$\dim \text{supp } \mathcal{H}^{-i}(\mathcal{F}^\bullet) \leq i, \quad \text{for all } i \in \mathbb{Z}.$$

(Unless otherwise specified, throughout the paper  $\dim$  will denote the complex dimension of a complex algebraic variety.) Perverse sheaves form an abelian category  $\text{Perv}(X; \mathbb{C})$ , and can be thought of as singular versions of local systems. Indeed, a local system  $L$  on a smooth complex  $n$ -dimensional variety yields a perverse sheaf  $L[n]$ ; conversely, a perverse sheaf restricts to a (shifted) local system on some dense open subvariety. More details on the theory of perverse sheaves can be found, e.g., in [BBD82], [CM09], [Di04], or [M18].

We mention here the following important examples of perverse sheaves:

- (i) If  $X$  is a smooth complex algebraic variety of pure dimension  $n$ , then the shifted constant sheaf  $\mathbb{C}_X[n]$  is a perverse sheaf on  $X$ .
- (ii) If  $X$  is a complex algebraic variety of pure dimension  $n$ , which moreover is a local complete intersection, then  $\mathbb{C}_X[n]$  is a perverse sheaf on  $X$ .
- (iii) If  $X$  is a complex algebraic variety of pure dimension  $n$ , then the Goresky-MacPherson *intersection cohomology complex*  $IC_X$  (see [GM83]) is a perverse sheaf on  $X$ . If, moreover,  $X$  is a rational homology manifold then  $IC_X \simeq \mathbb{C}_X[n]$ .

Let  $f : Y \rightarrow X$  be a proper surjective algebraic morphism, with  $Y$  smooth and of (complex) pure dimension  $n$ . Such a map can be *stratified*, which (roughly speaking) means that there is a stratification  $X = \sqcup_\lambda S_\lambda$  of  $X$  so that the restriction  $f^{-1}(S_\lambda) \rightarrow S_\lambda$  of  $f$  above each stratum  $S_\lambda$  is a topologically locally trivial fibration. For all  $\lambda$ , let  $s_\lambda \in S_\lambda$  denote a point in the stratum  $S_\lambda$ . The map  $f$  is called *semi-small* if, for all  $\lambda$ , one has:

$$(3) \quad \dim S_\lambda + 2 \dim f^{-1}(s_\lambda) \leq \dim X.$$

Of course, closed embeddings or finite maps are semi-small (onto their image). The map  $f$  is called *small* if the above inequality is strict for all positive codimension strata  $S_\lambda$ . Note that a semi-small map is finite on each open stratum of  $X$ , hence  $\dim Y = \dim X$ . It is also not difficult to see that, in the above notations, the map  $f$  is semi-small if, and only if,  $Rf_*(\mathbb{C}_Y[n])$  is a perverse sheaf on  $X$ . Finally, it should be noted that many algebraic maps are not (semi-)small. For example, the blow-up of  $\mathbb{C}^k \subset \mathbb{C}^n$ ,  $k \leq n - 2$ , is semi-small if, and only if,  $k = n - 2$ , and none of these maps is small.

**2.4. Jump loci via constructible complexes.** Back to cohomology jump loci, we note that by the projection formula and (2), for all  $\rho \in \text{Char}(X) \cong \text{Char}(\text{Alb}(X))$  we have:

$$(4) \quad H^i(X, L_\rho) \cong H^i(X, \mathbb{C}_X \otimes L_\rho) \cong H^i(\text{Alb}(X), (R\text{alb}_* \mathbb{C}_X) \otimes L_\rho),$$

where  $R\text{alb}_* : D_c^b(X; \mathbb{C}) \rightarrow D_c^b(\text{Alb}(X); \mathbb{C})$  denotes the derived pushforward. If, moreover, the Albanese map  $\text{alb} : A \rightarrow \text{Alb}(X)$  is proper (e.g., if  $X$  is projective), then the BBDG decomposition theorem [BBD82] yields that  $R\text{alb}_* \mathbb{C}_X$  is a direct sum of (shifted) perverse sheaves. In view of (4), this motivates the study of *cohomology jump loci of constructible complexes* (resp., *perverse sheaves*) on semi-abelian varieties.

**Definition 2.5.** Let  $\mathcal{F}^\bullet \in D_c^b(G; \mathbb{C})$  be a bounded constructible complex of  $\mathbb{C}$ -sheaves on a semi-abelian variety  $G$ . The *degree  $i$  cohomology jump locus of  $\mathcal{F}^\bullet$*  is defined as:

$$\mathcal{V}^i(G, \mathcal{F}) := \{\rho \in \text{Char}(G) \mid H^i(G, \mathcal{F}^\bullet \otimes_{\mathbb{C}} L_\rho) \neq 0\}.$$

With the above definition, (4) yields that:

$$(5) \quad \mathcal{V}^i(X) = \mathcal{V}^i(\text{Alb}(X), R\text{alb}_* \mathbb{C}_X).$$

### 3. MELLIN TRANSFORMATION AND APPLICATIONS

**3.1. Mellin transformation.** Let  $G$  be a semi-abelian variety defined by an extension

$$1 \rightarrow T \rightarrow G \rightarrow A \rightarrow 1,$$

where  $A$  is an abelian variety of dimension  $g$  and  $T \cong (\mathbb{C}^*)^m$  is a complex affine torus of dimension  $m$ . Set

$$\Gamma_G := \mathbb{C}[\pi_1(G)] \cong \mathbb{C}[t_1^{\pm 1}, \dots, t_{m+2g}^{\pm 1}],$$

and note that

$$\text{Char}(G) \cong \text{Spec } \Gamma_G.$$

Let  $\mathcal{L}_G$  be the (universal) rank-one local system of  $\Gamma_G$ -modules on  $G$ , defined by mapping the generators of  $\pi_1(G) \cong \mathbb{Z}^{m+2g}$  to the multiplication by the corresponding variables of  $\Gamma_G$ .

**Definition 3.1.** [GL96] The *Mellin transformation*  $\mathcal{M}_* : D_c^b(G; \mathbb{C}) \rightarrow D_{coh}^b(\Gamma_G)$  is given by

$$\mathcal{M}_*(\mathcal{F}^\bullet) := Ra_*(\mathcal{L}_G \otimes_{\mathbb{C}} \mathcal{F}^\bullet),$$

where  $a : G \rightarrow pt$  is the constant map to a point space, and  $D_{coh}^b(\Gamma_G)$  denotes the bounded coherent complexes of  $\Gamma_G$ -modules.

The Mellin transformation can be used to completely characterize perverse sheaves on complex affine tori. More precisely, one has the following result due to Gabber-Loeser [GL96, Theorem 3.4.1 and Theorem 3.4.7] in the  $\ell$ -adic context, and then extended to the present form in [LMW18a, Theorem 3.2]:

**Theorem 3.2.** *A constructible complex  $\mathcal{F}^\bullet \in D_c^b(T; \mathbb{C})$  on a complex affine torus  $T$  is perverse if, and only if,*

$$H^i(\mathcal{M}_*(\mathcal{F}^\bullet)) = 0 \text{ for all } i \neq 0.$$

In the context of abelian varieties, the Mellin transformation was considered in [BSS17] for proving generic vanishing statements:

**Theorem 3.3.** [BSS17] *For any  $\mathbb{C}$ -perverse sheaf  $\mathcal{P}$  on an abelian variety  $A$ , one has:*

$$H^i(\mathcal{M}_*(\mathcal{P})) = 0 \text{ for } i < 0.$$

and

$$H^i(D_{\Gamma_A}(\mathcal{M}_*(\mathcal{P}))) = 0 \text{ for } i < 0.$$

Here  $D_{\Gamma_A}(-) := \mathrm{RHom}_{\Gamma_A}(-, \Gamma_A)$  is the dualizing functor for the ring  $\Gamma_A = \mathbb{C}[\pi_1(A)]$ .

This result was recently extended to the semi-abelian context in [LMW18b], by induction on the dimension of the complex affine torus  $T$ :

**Theorem 3.4.** [LMW18b, Theorem 4.3] *For any  $\mathbb{C}$ -perverse sheaf  $\mathcal{P}$  on a semi-abelian variety  $G$ , one has:*

$$H^i(\mathcal{M}_*(\mathcal{P})) = 0 \text{ for } i < 0,$$

and

$$H^i(D_{\Gamma_G}(\mathcal{M}_*(\mathcal{P}))) = 0 \text{ for } i < 0.$$

Here  $D_{\Gamma_G}(-) := \mathrm{RHom}_{\Gamma_G}(-, \Gamma_G)$  is the dualizing functor for  $\Gamma_G$ -modules.

**3.2. Propagation and codimension lower bound.** The Mellin transformation was used in [LMW18a], [LMW18b] to translate the question of understanding the cohomology jump loci of a constructible complex to a problem in commutative algebra. Specifically, by the projection formula, cohomology jump loci of  $\mathcal{F}^\bullet \in D_c^b(G; \mathbb{C})$  are determined by those of the Mellin transformation  $\mathcal{M}_*(\mathcal{F}^\bullet)$  of  $\mathcal{F}^\bullet$  as follows:

$$(6) \quad \mathcal{V}^i(G, \mathcal{F}^\bullet) = \mathcal{V}^i(\mathcal{M}_*(\mathcal{F}^\bullet)).$$

Here, if  $R$  is a Noetherian domain and  $E^\bullet$  is a bounded complex of  $R$ -modules with finitely generated cohomology, we set

$$\mathcal{V}^i(E^\bullet) := \{\mathfrak{p} \in \mathrm{Spec} R \mid H^i(F^\bullet \otimes_R R/\mathfrak{p}) \neq 0\},$$

with  $F^\bullet$  a bounded above finitely generated free resolution of  $E^\bullet$ . We also have the following:

**Proposition 3.5.** [BSS17, Lemma 2.8] *Let  $R$  be a regular Noetherian domain and  $E^\bullet$  a bounded complex of  $R$ -modules with finitely generated cohomology. Then  $H^i(E^\bullet) = 0$  for  $i < 0$  if, and only if,  $\mathrm{codim} \mathcal{V}^{-i}(E^\bullet) \geq i$  for  $i \geq 0$ .*

By using the identification (6), together with Proposition 3.5 and standard facts from commutative algebra, we proved in [LMW18b] the following result as a direct consequence of Theorem 3.4:

**Theorem 3.6.** [LMW18b, Theorem 4.6] *For any  $\mathbb{C}$ -perverse sheaf  $\mathcal{P}$  on a semi-abelian variety  $G$ , the cohomology jump loci of  $\mathcal{P}$  satisfy the following properties:*

(i) *Propagation:*

$$\mathcal{V}^{-m-g}(G, \mathcal{P}) \subseteq \cdots \subseteq \mathcal{V}^0(G, \mathcal{P}) \supseteq \mathcal{V}^1(G, \mathcal{P}) \supseteq \cdots \supseteq \mathcal{V}^g(G, \mathcal{P}).$$

Moreover,  $\mathcal{V}^i(G, \mathcal{P}) = \emptyset$  if  $i \notin [-m - g, g]$ .

(ii) *Codimension lower bound: for all  $i \geq 0$ ,*

$$\mathrm{codim} \mathcal{V}^i(G, \mathcal{P}) \geq i \quad \text{and} \quad \mathrm{codim} \mathcal{V}^{-i}(G, \mathcal{P}) \geq i.$$

**Remark 3.7.** Cohomology jump loci of constructible complexes can be defined for arbitrary field coefficients, and in fact Theorem 3.4 and Theorem 3.6 hold in this generality, see [LMW18b, Theorem 4.3, Theorem 4.6].

The result of Theorem 3.6 can be viewed as a topological counterpart of similar properties satisfied by the Green-Lazarsfeld algebraic jump loci of topologically trivial line bundles, see [GL87, GL91].

**Remark 3.8** (Equivalent formulation of the propagation property). Let  $\mathcal{P}$  be a  $\mathbb{C}$ -perverse sheaf so that not all  $H^j(G, \mathcal{P})$  are zero. Let

$$k_+ := \max\{j \mid H^j(G, \mathcal{P}) \neq 0\} \quad \text{and} \quad k_- := \min\{j \mid H^j(G, \mathcal{P}) \neq 0\}.$$

Then it's easy to see that the propagation property (i) is equivalent to:  $k_+ \geq 0$ ,  $k_- \leq 0$  and

$$H^j(G, \mathcal{P}) \neq 0 \iff k_- \leq j \leq k_+.$$

Moreover, if  $\mathcal{P}$  is a semi-simple perverse sheaf on an abelian variety  $G = A$ , then the Hard Lefschetz Theorem yields that  $k_- = -k_+$ . Then by the relative Hard Lefschetz theorem for the Albanese map, a similar interval of nonvanishing cohomology can be obtained for a simple perverse sheaf on a smooth complex projective variety; compare with [Wei16b, Corollary 1].

**3.3. Application: generic vanishing and signed Euler characteristic.** An important consequence of Theorem 3.6 is the following generic vanishing statement:

**Corollary 3.9.** *For any  $\mathbb{C}$ -perverse sheaf  $\mathcal{P}$  on a semi-abelian variety  $G$ ,*

$$H^i(G, \mathcal{P} \otimes_{\mathbb{C}} L_\rho) = 0$$

*for any generic rank-one  $\mathbb{C}$ -local system  $L_\rho$  and all  $i \neq 0$ . In particular,*

$$(7) \quad \chi(G, \mathcal{P}) := \sum_i (-1)^i \dim_{\mathbb{C}} H^i(G, \mathcal{P}) \geq 0.$$

*Moreover,  $\chi(G, \mathcal{P}) = 0$  if, and only if,  $\mathcal{V}^0(G, \mathcal{P}) \neq \mathrm{Char}(G)$ .*

*Proof.* If  $\rho \notin \bigcup_{i \neq 0} \mathcal{V}^i(G, \mathcal{P})$ , then  $H^i(G, \mathcal{P} \otimes_{\mathbb{C}} L_\rho) = 0$  for  $i \neq 0$ . The codimension bound in Theorem 3.6 shows that  $\bigcup_{i \neq 0} \mathcal{V}^i(G, \mathcal{P})$  has at least codimension one in  $\mathrm{Char}(G)$ , so the generic vanishing result follows. Moreover, for such a generic choice of character  $\rho$ , we have:

$$\chi(G, \mathcal{P}) = \chi(G, \mathcal{P} \otimes_{\mathbb{C}} L_\rho) = \dim_{\mathbb{C}} H^0(G, \mathcal{P} \otimes_{\mathbb{C}} L_\rho) \geq 0.$$

For the first equality, e.g., compare with [Kra14, Lemma 4.1]. The last claim follows directly from the propagation property.  $\square$

The above generic vanishing statement was originally proved by other methods in [Kra14, Theorem 2.1] in the  $\ell$ -adic context and further generalized to arbitrary field coefficients in [LMW17b, Theorem 1.1]. For abelian varieties, generic vanishing results were obtained in [KW15, Theorem 1.1], [Sch15, Corollary 7.5], [Wei16a, Vanishing Theorem] or [BSS17, Theorem 1.1]. The signed Euler characteristic property (7) is originally due to Franecki and Kapranov [FK00, Corollary 1.4].

**Remark 3.10.** The properties of perverse sheaves from Theorem 3.6 and Corollary 3.9 are collectively termed the *propagation package* for perverse sheaves on semi-abelian varieties.

**Example 3.11.** Let  $Z$  be a closed pure-dimensional subvariety of a semi-abelian variety  $G$ , with inclusion map  $j : Z \hookrightarrow G$ . Then  $j_*IC_Z \in \text{Perv}(G; \mathbb{C})$ , so (7) yields that

$$(8) \quad (-1)^{\dim Z} \chi_{IH}(Z) \geq 0,$$

where  $\chi_{IH}(Z) := \sum_{i \geq 0} (-1)^i \dim_{\mathbb{C}} IH^i(Z, \mathbb{C})$  is the intersection homology Euler characteristic of  $Z$ . If  $G = A$  is an abelian variety, a geometric proof of (8) was recently obtained in [EGM18] by using the stratified Morse theory of Georesky-MacPherson [GM88]; see also [BW15] for the case when  $G = T$  is a complex affine torus.

If the closed subvariety  $Z \subseteq G$  is smooth, or a rational homology manifold, or a local complete intersection, then  $j_*\mathbb{C}_Z[\dim Z] \in \text{Perv}(G; \mathbb{C})$ , so (7) yields in these cases that

$$(9) \quad (-1)^{\dim Z} \chi(Z) \geq 0.$$

For a geometric proof of (9) in the smooth case see [LMW17a], where the non-proper Morse theory of Palais-Smale [PS64] is used; see also [Hu13] for the case when  $G = T$  is a complex affine torus. If  $G = A$  is an abelian variety, then (9) is proved in the local complete intersection case in [EGM18] by stratified Morse theory techniques.

For completeness, and also in relation with Example 3.11, we also mention here the following version of the signed Euler characteristic property, as a special case of positivity results for characteristic classes obtained recently in [AMSS19], and which is already implicit in [FK00] and [TS10]:

**Theorem 3.12.** [AMSS19, FK00, TS10] *If  $Z$  is a closed subvariety of an abelian variety  $A$ , and  $\varphi$  is a constructible function on  $Z$  with effective characteristic cycle, then*

$$(10) \quad \chi(Z, \varphi) \geq 0.$$

In order to explain the meaning of Theorem 3.12 and how it relates to (8) and (9), let us first recall some terminology (where we can replace  $A$  by a smooth complex algebraic variety). A function  $\varphi : Z \rightarrow \mathbb{Z}$  is *constructible* if there is a Whitney stratification  $\mathcal{Z}$  of  $Z$  so that  $\varphi$  is constant on each connected component of strata  $S \in \mathcal{Z}$ . The Euler characteristic of such a constructible function  $\varphi$  is defined by

$$\chi(Z, \varphi) := \sum_{S \in \mathcal{Z}} \chi(S) \cdot \varphi(S),$$

where  $\varphi(S)$  denotes the (constant) value of  $\varphi$  on the stratum  $S$ .

To a constructible complex  $\mathcal{F}^\bullet \in D_c^b(Z; \mathbb{C})$  one associates a constructible function  $\chi_{st}(\mathcal{F}^\bullet)$  defined by taking stalkwise Euler characteristics, i.e.,

$$\chi_{st}(\mathcal{F}^\bullet)(x) := \chi(\mathcal{F}_x^\bullet).$$

For example,  $\chi_{st}(\mathbb{C}_Z) = 1_Z$  and we let  $ic_Z := \chi_{st}(IC_Z)$ . Note that if  $\varphi = \chi_{st}(\mathcal{F}^\bullet)$ , then  $\chi(Z, \varphi) = \chi(Z, \mathcal{F}^\bullet)$ . Another important example of a constructible function is the *local Euler obstruction* function  $Eu_Z$  of MacPherson [Mac74], which is an essential ingredient in the definition of Chern classes for singular varieties.

To a constructible function  $\varphi$  on  $Z \subseteq A$ , one associates a *characteristic cycle*

$$(11) \quad CC(\varphi) = \sum_{Y \subseteq Z} a_Y [T_Y^* A] \in L(T^* A|_Z),$$

for uniquely determined closed subvarieties  $Y$  of  $Z$  and non-zero integer coefficients  $a_Y$ . Here,  $L(T^* A|_Z)$  denotes the group of conic Langrangian cycles in the cotangent bundle  $T^* A$  with support on  $Z$ , and  $T_Y^* A$  is the conormal space of  $Y$ , i.e., the closure in  $T^* A$  of the conormal bundle of the smooth locus of  $Y$ . For example, if  $Z \subseteq A$  is a closed and irreducible subvariety, then:

$$(12) \quad CC(Eu_Z) = (-1)^{\dim Z} [T_Z^* A].$$

In particular, by (12), the coefficients  $a_Y$  in (11) are determined by:

$$(13) \quad 0 \neq \varphi = \sum_Y a_Y (-1)^{\dim Y} Eu_Y.$$

The characteristic cycle of  $\varphi \neq 0$  is *effective* if, and only if, the coefficients  $a_Y$  are all positive. For example, if  $\varphi = (-1)^{\dim Z} Eu_Z$ , then (12) yields that  $CC(\varphi) = [T_Z^* A]$ , which is clearly effective. Therefore, Theorem 3.12 yields the following:

**Corollary 3.13.** *If  $Z$  is a closed irreducible subvariety of an abelian variety  $A$ , then*

$$(14) \quad (-1)^{\dim Z} \chi(Z, Eu_Z) \geq 0.$$

It is also known that if  $0 \neq \varphi = \chi_{st}(\mathcal{P})$  is a nontrivial constructible function associated to a perverse sheaf  $\mathcal{P}$  on  $Z$ , then  $CC(\varphi)$  is effective. In particular,  $CC(ic_Z)$  is effective, so Theorem 3.12 recovers (8) in the abelian context. Similarly, if  $Z \subseteq A$  is smooth, or a rational homology manifold, or a local complete intersection, then  $\mathbb{C}_Z[\dim Z] \in Perv(Z)$ , so Theorem 3.12 recovers (9) in the abelian context.

Finally, it is shown in [AMSS19, Proposition 1.14] that if  $p : G \rightarrow A$  is the projection from a semi-abelian variety onto its abelian part, then  $p$  has the following property: if a constructible function  $\varphi$  on  $G$  is associated to a perverse sheaf, then its pushforward  $p_*(\varphi)$  (as a constructible function on  $A$ ) also comes from a perverse sheaf, so  $p_*(\varphi)$  has an effective characteristic cycle. In particular, an application of Theorem 3.12 yields that if  $\mathcal{P}$  is a perverse sheaf on  $G$  with associated constructible function  $\varphi$  then:

$$\chi(G, \mathcal{P}) = \chi(G, \varphi) = \chi(A, p_*(\varphi)) \geq 0,$$

thus reproving (7); see [AMSS19, Corollary 1.16].

**3.4. Application: homological duality.** Abelian duality spaces were introduced in [DSY15], by analogy with the duality spaces of Bieri-Eckmann [BE73]. They are especially useful for explaining some previously conjectural behavior of the cohomology of abelian representations.

Let  $X$  be a finite connected CW complex, with  $\pi := \pi_1(X)$  and  $H := H_1(X, \mathbb{Z})$ . There is a canonical  $\mathbb{Z}[H]$ -local system on  $X$ , whose monodromy action is given by the composition of the quotient  $\pi \rightarrow \pi^{ab} = H$  with the natural multiplication  $H \times \mathbb{Z}[H] \rightarrow \mathbb{Z}[H]$ .

**Definition 3.14.** [DSY15] A finite connected CW complex  $X$  is an *abelian duality space* of dimension  $n$  if  $H^i(X, \mathbb{Z}[H]) = 0$  for all  $i \neq n$ , and  $H^n(X, \mathbb{Z}[H])$  is non-zero and torsion-free (as a  $\mathbb{Z}$ -module).

When  $X$  is compact, Definition 3.14 is equivalent to the requirement that the integral compactly supported cohomology of the universal abelian cover of an abelian duality space  $X$  is concentrated in a single dimension,  $n$ , where it is torsion-free.

A *duality space* [BE73] is defined similarly, by using  $\pi$  instead of  $H$  in the above definition (hence by replacing the universal abelian cover by the universal cover).

Duality spaces and abelian duality spaces enjoy (homological) duality properties similar to the Serre duality for projective varieties.

A very natural question to investigate is the following *realization problem* for (abelian) duality spaces:

**Question 3.15.** Which smooth complex quasi-projective varieties are (abelian) duality spaces?

For example, there are plenty of smooth complex projective varieties which are duality spaces (e.g., all smooth complex projective curves of genus  $g \geq 1$ ), but, as will be explained below, smooth complex projective varieties which are abelian duality spaces are rather rare (e.g., among smooth complex projective curves, only genus 1 curves are abelian duality spaces).

Obstructions to the realizability of abelian duality spaces referred to in Question 3.15 are provided by the following result (see [DSY15], [LMW18a]):

**Theorem 3.16.** *Let  $X$  be an abelian duality space of dimension  $n$ . For simplicity, assume that  $H_1(X, \mathbb{Z})$  is free<sup>1</sup>. Then the cohomology jump loci of  $X$  satisfy a propagation package, i.e., the following properties hold:*

(i) *Propagation property:*

$$\mathcal{V}^n(X) \supseteq \mathcal{V}^{n-1}(X) \supseteq \cdots \supseteq \mathcal{V}^0(X).$$

(ii) *Codimension lower bound: for all  $i \geq 0$ ,*

$$\text{codim } \mathcal{V}^{n-i}(X) = b_1(X) - \dim \mathcal{V}^{n-i}(X) \geq i.$$

(iii) *Surviving property: If  $V$  is an irreducible component of  $\mathcal{V}^n(X)$  of codimension  $d$ , then  $V \subset \mathcal{V}^{n-d}(X)$ . In particular,  $V$  is also an irreducible component of  $\mathcal{V}^{n-d}(X)$ .*

(iv) *Generic vanishing:  $H^i(X, L_\rho) = 0$  for  $\rho \in \text{Char}(X)$  generic and all  $i \neq n$ .*

(v) *Signed Euler characteristic property:*

$$(-1)^n \chi(X) \geq 0.$$

(vi) *Betti property:  $b_i(X) > 0$ , for  $0 \leq i \leq n$ , and  $b_1(X) \geq n$ .*

*Proof.* We only indicate here a proof for the Betti property (vi). By Remark 2.2(a), we have that  $\mathcal{V}^0(X) = \{\mathbb{C}_X\}$  is just one point. Then the propagation property (ii) yields that

<sup>1</sup>The statement remains true without any assumption on  $H_1(X, \mathbb{Z})$ , but in this generality one needs to consider all characters of  $\pi_1(X)$ , i.e., all elements of  $\text{Hom}(\pi_1(X), \mathbb{C}^*)$ , and the corresponding cohomology jump loci; see [LMW18a, Theorem 4.6] for details.

$\mathbb{C}_X \in \mathcal{V}^i(X)$  for  $0 \leq i \leq n$ , hence  $b_i(X) > 0$  for  $0 \leq i \leq n$ . Furthermore, the codimension bound (ii) for  $\mathcal{V}^0(X)$  shows that  $b_1(X) - \dim \mathcal{V}^0(X) \geq n$ , hence  $b_1(X) \geq n$ .  $\square$

As a direct application of the propagation package of Theorem 3.16, in [LMW18a] we gave a complete answer to the abelian duality realization problem of Question 3.15 in the projective setting:

**Theorem 3.17.** [LMW18a, Theorem 6.1] *A smooth complex projective variety  $X$  is an abelian duality space if, and only if,  $X$  is an abelian variety. Moreover, a compact Kähler manifold is an abelian duality space if, and only if, it is a compact complex torus.*

Indeed, in this case, Poincaré duality imposes additional obstructions on the cohomology jump loci of  $X$ , which, when combined with the propagation property, imply that the Albanese map  $\text{alb} : X \rightarrow \text{Alb}(X)$  is a finite covering, hence an isomorphism (compare also with Question 4.11 below).

Theorem 3.17 provides a new topological characterization of compact complex tori and, respectively, abelian varieties in terms of homological duality properties, and can be viewed as a topological counterpart of the Chen-Hacon *birational* characterization of abelian varieties [CH01].

In relation to Theorem 3.17, one can also ask the following:

**Question 3.18.** Does there exist a closed orientable manifold that is an abelian duality space, but not a real torus?

Furthermore, by interpreting the abelian duality property in terms of the Mellin transformation, we identified in [LMW18b] a very general class of complex algebraic varieties which can be realized as abelian duality spaces:

**Theorem 3.19.** [LMW18b, Theorem 7.11] *Let  $X$  be an  $n$ -dimensional smooth complex quasi-projective variety, which is homotopy equivalent to a CW complex of real dimension  $n$  (e.g.,  $X$  is affine). Assume that the Albanese map  $\text{alb}$  of  $X$  is proper and semi-small (e.g., a finite map or a closed embedding), or  $\text{alb}$  is quasi-finite. Then  $X$  is an abelian duality space of dimension  $n$ .*

*Proof.* Let us briefly sketch the main idea of the proof. For simplicity, assume that  $H_1(X, \mathbb{Z})$  is a free abelian group. The assumption that  $X$  is homotopy equivalent to an  $n$ -dimensional CW complex implies that  $H^i(X, \mathbb{Z}[H]) = 0$  for all  $i > n$ . On the other hand, it is easy to show that

$$H^i(\mathcal{M}_*(R \text{alb}_* \mathbb{K}_X)) \cong H^i(X, \mathbb{K}[H])$$

for all  $i \in \mathbb{Z}$ . Here  $\mathbb{K}$  is an arbitrary field of coefficients, and  $\mathbb{K}_X$  is the corresponding constant sheaf on  $X$ . Since the hypotheses of the theorem imply that  $R \text{alb}_*(\mathbb{K}_X[n])$  is  $\mathbb{K}$ -perverse on  $\text{Alb}(X)$ , Theorem 3.4 and Remark 3.7 yield that  $H^i(X, \mathbb{K}[H]) = 0$  for  $i < n$ . Using a universal coefficient theorem type of argument, one can then show that  $H^i(X, \mathbb{Z}[H]) = 0$  for  $i \neq n$  and  $H^n(X, \mathbb{Z}[H])$  is torsion free as a  $\mathbb{Z}$ -module.  $\square$

Let us next discuss a few examples.

**Example 3.20** (Very affine manifolds). Let  $X$  be an  $n$ -dimensional *very affine manifold*, i.e., a smooth closed subvariety of a complex affine torus  $T = (\mathbb{C}^*)^m$  (e.g., the

complement of an essential hyperplane arrangement or the complement of a toric arrangement). The closed embedding  $i : X \hookrightarrow T$  is a proper semi-small map, and hence the Albanese map  $\text{alb} : X \rightarrow \text{Alb}(X)$  is also proper and semi-small. Since  $X$  is affine and  $n$ -dimensional, it has the homotopy type of a finite CW complex of real dimension  $n$ . Therefore, we get by Theorem 3.19 that  $X$  is an abelian duality space of dimension  $n$ . In particular, very affine manifolds satisfy the propagation package of Theorem 3.16.

**Example 3.21.** Let  $Y$  be a smooth complex projective variety, and let  $\mathcal{L}$  be a very ample line bundle on  $Y$ . Consider an  $N$ -dimensional sub-linear system  $|E|$  of  $|\mathcal{L}|$  such that  $E$  is base point free over  $Y$ . Then a basis  $\{s_0, s_1, \dots, s_N\}$  of  $E$  gives a well-defined morphism

$$\varphi_{|E|} : Y \rightarrow \mathbb{CP}^N.$$

Each  $\{s_i = 0\}$  defines a hypersurface  $V_i$  in  $Y$ . In particular,  $\bigcap_{i=0}^N V_i = \emptyset$ . Then  $\varphi_{|E|}$  is a finite morphism; for a proof, see [LMW18a, Example 5.4]. Taking the restriction  $f$  of  $\varphi_{|E|}$  over  $X = Y \setminus \bigcup_{i=0}^N V_i$ , we get a map

$$f := \left( \frac{s_1}{s_0}, \frac{s_2}{s_0}, \dots, \frac{s_N}{s_0} \right) : X \longrightarrow T = (\mathbb{C}^*)^N$$

which is finite, hence proper and semi-small. This implies that the Albanese map  $\text{alb}$  is also proper and semi-small. Theorem 3.19 yields that  $X$  is an abelian duality space.

This example shows that there are plenty of smooth quasi-projective varieties which are abelian duality spaces. If all hypersurfaces  $V_i$  are smooth and intersect locally like hyperplanes, then this example is a special case of [DS17, Theorem 1.1]. However, here we do not make any assumptions on the singularities of the  $V_i$ 's and of their intersections.

**Example 3.22** (Elliptic arrangement complements). It was shown in [DS17, DSY15] that the complement of an *elliptic arrangement* is an abelian duality space. This fact also follows from Theorem 3.19 as follows. Let  $E$  be an elliptic curve, and let  $\mathcal{A}$  be an essential elliptic arrangement in  $E^n$  with complement  $X := E^n \setminus \mathcal{A}$ . Then  $X$  is a complex  $n$ -dimensional affine variety, and by the universal property of the Albanese map, the natural embedding  $X \hookrightarrow E^n$  factors through  $\text{alb} : X \rightarrow \text{Alb}(X)$ . Hence the Albanese map  $\text{alb} : X \rightarrow \text{Alb}(X)$  is also an embedding (hence, in particular, quasi-finite). So Theorem 3.19 applies to show that  $X$  is an abelian duality space of dimension  $n$ .

The affine assumption is a sufficient but not a necessary condition for an  $n$ -dimensional smooth complex quasi-projective variety to be homotopy equivalent to a finite CW-complex of real dimension  $n$ . The following is an example of an  $n$ -dimensional smooth complex quasi-projective variety which is an abelian duality space of dimension  $n$ , but which is not affine.

**Example 3.23.** Let  $X$  be the blowup of  $(\mathbb{C}^*)^2$  at a point. The Albanese map for  $X$  is the blowdown map  $X \rightarrow (\mathbb{C}^*)^2$ , which is proper and semi-small. Moreover,  $X$  is homotopy equivalent to the 2-dimensional CW-complex  $T^2 \vee S^2$ , where  $T^2 = S^1 \times S^1$  is the real 2-dimensional torus. Thus, Theorem 3.19 shows that  $X$  is an abelian duality space of dimension 2. However,  $X$  is not affine because it contains a closed subvariety  $\mathbb{CP}^1$ .

If an  $n$ -dimensional smooth complex quasi-projective variety  $X$  is an abelian duality space and  $\text{alb} : X \rightarrow \text{Alb}(X)$  is proper, then  $\text{alb}$  is semi-small (onto its image). Indeed, by using the decomposition theorem and the relative hard Lefschetz theorem, one can readily see that  $R\text{alb}_*(\mathbb{C}_X[n])$  is a perverse sheaf. We conjecture that, in some sense, the converse of Theorem 3.19 is also true.

**Conjecture 3.24.** *Let  $X$  be an  $n$ -dimensional smooth complex quasi-projective variety with proper Albanese map  $\text{alb} : X \rightarrow \text{Alb}(X)$ . Then  $X$  is an abelian duality space of dimension  $n$  if, and only if,  $\text{alb}$  is semi-small and  $X$  is homotopy equivalent to a finite CW complex of real dimension  $n$ .*

It is also natural to investigate topological properties of the Bieri-Eckmann duality spaces. We formulate here the following:

**Question 3.25.** If  $X$  is a smooth complex quasi-projective variety which is a duality space, what can be said about its topology? For example, is the Euler characteristic of  $X$  signed?

The second part of Question 3.25 is motivated by the *Hopf and Singer conjectures*, e.g., see [Lu02, Ch.11] for an overview. Hopf conjectured that if  $M$  is a closed manifold of real dimension  $2n$ , with negative sectional curvature, then  $(-1)^n \chi(M) \geq 0$ . Jost-Zuo [JZ00] proved Hopf's conjecture in the Kähler context. More precisely, they showed that if  $M$  is a compact Kähler manifold of complex dimension  $n$  and non-positive sectional curvature, then  $(-1)^n \chi(M) \geq 0$ . Hopf's conjecture was strengthened by Singer, who claimed that if  $M^{2n}$  is a closed *aspherical* manifold (i.e., a manifold having a contractible universal cover), then  $(-1)^n \chi(M) \geq 0$ . (Note that if  $M$  carries a Riemannian metric with non-positive sectional curvature, then  $M$  is aspherical by Hadamard's Theorem.) In [LMW18a], we proved the following result:

**Proposition 3.26.** *A closed oriented manifold is a duality space if, and only if, it is aspherical.*

In particular, Proposition 3.26 provides a reformulation of Singer's conjecture from the point of view of homological duality.

#### 4. CHARACTERIZATION OF PERVERSE SHEAVES AND APPLICATIONS

**4.1. Characterization of perverse sheaves.** In this last section, we touch upon MacPherson's quote mentioned in the Introduction, and present a complete (global) characterization of perverse sheaves on semi-abelian varieties; see [LMW18b] for complete details. Motivation is also provided by the following result of Schnell:

**Theorem 4.1.** [Sch15] *If  $A$  is an abelian variety and  $\mathcal{F}^\bullet \in D_c^b(A; \mathbb{C})$ , then  $\mathcal{F}^\bullet$  is perverse if, and only if, for all  $i \in \mathbb{Z}$ ,  $\text{codim } \mathcal{V}^i(A, \mathcal{F}^\bullet) \geq |2i|$ .*

Furthermore, as a consequence of Theorem 3.2, Proposition 3.5 and Artin's vanishing theorem, one gets the following:

**Theorem 4.2.** [LMW18b, Corollary 6.8]  *$\mathcal{F}^\bullet \in D_c^b(T; \mathbb{C})$  is perverse on a complex affine torus  $T$  if, and only if,*

- (i) For all  $i > 0$ :  $\mathcal{V}^i(T, \mathcal{F}^\bullet) = \emptyset$ , and
- (ii) For all  $i \leq 0$ :  $\text{codim } \mathcal{V}^i(T, \mathcal{F}^\bullet) \geq -i$ .

In order to unify and generalize the results of Theorems 4.1 and 4.2 to the semi-abelian context, we need to recall a structure result for the cohomology jump loci of constructible complexes on a semi-abelian variety  $G$ , which has been recently obtained by Budur-Wang in [BW17]; see also [Sch15, Theorem 2.2] for the abelian case.

**Definition 4.3.** A closed irreducible subvariety  $V$  of  $\text{Char}(G)$  is called *linear* if there exists a short exact sequence of semi-abelian varieties

$$1 \rightarrow G''(V) \rightarrow G \xrightarrow{q} G'(V) \rightarrow 1$$

and some  $\rho \in \text{Char}(G)$  such that

$$V := \rho \cdot \text{Im}(q^\# : \text{Char}(G'(V)) \rightarrow \text{Char}(G)).$$

Here  $G''(V)$  and  $G'(V)$  depend on  $V$ , and  $q^\#$  is corresponding map induced by  $q : G \rightarrow G'(V)$ .

With the above definition, one has the following result:

**Theorem 4.4.** [BW17] *For any  $\mathcal{F}^\bullet \in D_c^b(G; \mathbb{C})$ , each jump locus  $\mathcal{V}^i(G, \mathcal{F}^\bullet)$  is a finite union of linear subvarieties of  $\text{Char}(G)$ .*

**Definition 4.5.** Let  $G$  be a semi-abelian variety and let  $V$  be an irreducible linear subvariety of  $\text{Char}(G)$ . In the notations of Definition 4.3, let  $T''(V)$  and  $A''(V)$  denote the complex affine torus and, resp., the abelian variety part of  $G''(V)$ . Define:

$$\begin{aligned} \text{abelian codimension: } \text{codim}_a V &:= \dim A''(V), \\ \text{semi-abelian codimension: } \text{codim}_{sa} V &:= \dim G''(V). \end{aligned}$$

These definitions generalize to reducible subvarieties by taking the minimum among all irreducible components.

**Remark 4.6.** Let  $V$  be a nonempty linear subvariety of  $\text{Spec } \Gamma_G$ .

- (1) If  $G = T$  is a complex affine torus, then:  $\text{codim}_{sa} V = \text{codim } V$  and  $\text{codim}_a V = 0$ .
- (2) If  $G = A$  is an abelian variety, we have:  $\text{codim}_{sa}(V) = \text{codim}_a(V) = \frac{1}{2} \text{codim}(V)$ .

In particular, Theorem 4.1 can be restated as follows:  $\mathcal{F}^\bullet \in D_c^b(A; \mathbb{C})$  is perverse if, and only if, for all  $i \in \mathbb{Z}$ ,  $\text{codim}_a \mathcal{V}^i(A, \mathcal{F}^\bullet) \geq |i|$ .

In the above notations, the following generalization of Schnell's result was obtained in [LMW18b]:

**Theorem 4.7.** [LMW18b, Theorem 6.6] *A constructible complex  $\mathcal{F}^\bullet \in D_c^b(G; \mathbb{C})$  is perverse on  $G$  if, and only if,*

- (i)  $\text{codim}_a \mathcal{V}^i(G, \mathcal{F}^\bullet) \geq i$  for all  $i \geq 0$ , and
- (ii)  $\text{codim}_{sa} \mathcal{V}^i(G, \mathcal{F}^\bullet) \geq -i$  for all  $i \leq 0$ .

*Proof.* The “only if” part is proved by induction on  $\dim T$ , using Theorem 4.1 as the beginning step of the induction process. For the “if” part, one shows that the two codimension lower bounds in the statement of Theorem 4.7 are sharp. For complete details, see [LMW18b, Section 6].  $\square$

**4.2. Application: cohomology jump loci of quasi-projective manifolds.** The results of Theorem 3.6, Theorem 4.7 and Corollary 3.9 can be directly applied for the study of cohomology jump loci  $\mathcal{V}^i(X) \subseteq \text{Char}(X) = \text{Char}(\text{Alb}(X))$  of a smooth quasi-projective variety  $X$ . More precisely, we have the following (see [LMW18b, Corollary 7.2] for a more general formulation):

**Corollary 4.8.** *Let  $X$  be a smooth quasi-projective variety of complex dimension  $n$ . Assume that  $R\text{alb}_*(\mathbb{C}_X[n])$  is a perverse sheaf on  $\text{Alb}(X)$  (e.g.,  $\text{alb}$  is proper and semi-small, or  $\text{alb}$  is quasi-finite). Then the cohomology jump loci  $\mathcal{V}^i(X)$  have the following properties:*

(1) *Propagation property:*

$$\mathcal{V}^n(X) \supseteq \mathcal{V}^{n-1}(X) \supseteq \cdots \supseteq \mathcal{V}^0(X) = \{1\};$$

$$\mathcal{V}^n(X) \supseteq \mathcal{V}^{n+1}(X) \supseteq \cdots \supseteq \mathcal{V}^{2n}(X).$$

(2) *Codimension lower bound: for all  $i \geq 0$ ,*

$$\text{codim}_{sa} \mathcal{V}^{n-i}(X) \geq i \quad \text{and} \quad \text{codim}_a \mathcal{V}^{n+i}(X) \geq i.$$

(3) *Generic vanishing:  $H^i(X, L_\rho) = 0$  for generic  $\rho \in \text{Char}(X)$  and all  $i \neq n$ .*

(4) *Signed Euler characteristic property:  $(-1)^n \chi(X) \geq 0$ .*

(5) *Betti property:  $b_i(X) > 0$  for all  $i \in [0, n]$ , and  $b_1(X) \geq n$ .*

**Example 4.9.** Let  $X$  be a smooth closed sub-variety of a semi-abelian variety  $G$  (e.g.,  $X$  is a very affine manifold as in Example 3.20, or a smooth projective curve as in Example 2.4). The closed embedding  $i : X \hookrightarrow G$  is a proper semi-small map, and hence the Albanese map  $\text{alb} : X \rightarrow \text{Alb}(X)$  is also proper and semi-small. Then  $R\text{alb}_*(\mathbb{C}_X[\dim X])$  is a perverse sheaf on  $\text{Alb}(X)$ . Hence the jump loci of  $X$  satisfy the properties listed in the above corollary.

**4.3. Application: topological characterization of semi-abelian varieties.** The Structure Theorem 4.4 and the propagation package of Theorem 3.6 and Corollary 3.9 can be used to give the following topological characterization of semi-abelian varieties (see [LMW18b, Proposition 7.7]):

**Corollary 4.10.** *Let  $X$  be a smooth quasi-projective variety with proper Albanese map (e.g.,  $X$  is projective), and assume that  $X$  is homotopy equivalent to a real torus. Then  $X$  is isomorphic to a semi-abelian variety.*

*Proof.* Assume  $X$  has complex dimension  $n$ . By the Decomposition Theorem [BBD82],  $R\text{alb}_*(\mathbb{C}_X[n])$  is a direct sum of shifted semi-simple perverse sheaves on  $\text{Alb}(X)$ . Denote by  $\mathcal{S}$  the collection of all simple summands appearing (up to a shift) in  $R\text{alb}_*(\mathbb{C}_X[n])$ . Then, by using Theorem 3.6(i) and the identification (5), we have that

$$(15) \quad \bigcup_{i=0}^{2n} \mathcal{V}^i(X) = \bigcup_{\mathcal{P} \in \mathcal{S}} \mathcal{V}^0(\text{Alb}(X), \mathcal{P}).$$

Since  $X$  is homotopy equivalent to a real torus, Example 2.3 shows that  $\bigcup_{i=0}^{2n} \mathcal{V}^i(X)$  is just an isolated point. Hence, by (15), for every simple perverse sheaf  $\mathcal{P} \in \mathcal{S}$ , the

jump locus  $\mathcal{V}^0(\mathrm{Alb}(X), \mathcal{P})$  is exactly this isolated point, so Corollary 3.9 yields that  $\chi(\mathrm{Alb}(X), \mathcal{P}) = 0$ .

Simple perverse sheaves with zero Euler characteristic on semi-abelian varieties are completely described in [LMW18b, Theorem 5.5] by using the structure Theorem 4.4 and the propagation package for their cohomology jump loci. In particular, it follows that for all  $\mathcal{P} \in \mathcal{S}$  we get:  $\mathcal{P} = \mathbb{C}_{\mathrm{Alb}(X)}[\dim \mathrm{Alb}(X)]$ . So  $R\mathrm{alb}_* \mathbb{C}_X$  is a direct sum of shifted rank-one constant sheaves on  $\mathrm{Alb}(X)$ . Since  $X$  and  $\mathrm{Alb}(X)$  are both homotopy equivalent to tori, and since  $b_1(X) = b_1(\mathrm{Alb}(X))$ , we have that  $b_i(X) = b_i(\mathrm{Alb}(X))$  for all  $i$ . Therefore,

$$R\mathrm{alb}_* \mathbb{C}_X \cong \mathbb{C}_{\mathrm{Alb}(X)}.$$

Since  $\mathrm{alb}$  is proper, it follows that all fibers of  $\mathrm{alb}$  are zero-dimensional. Then it can be seen easily that  $\mathrm{alb}$  is in fact an isomorphism.  $\square$

Under the assumptions of Corollary 4.10, we showed that the Albanese map  $\mathrm{alb} : X \rightarrow \mathrm{Alb}(X)$  is an isomorphism. This motivates the following:

**Problem 4.11.** Find necessary and sufficient conditions on the cohomology jump loci of  $X$  so that the Albanese map  $\mathrm{alb} : X \rightarrow \mathrm{Alb}(X)$  is an isomorphism, or a dominant map, or a submersion.

For example, we showed in [LMW18b, Corollary 7.4] that if  $X$  is an  $n$ -dimensional smooth quasi-projective variety so that  $\bigcup_{i=0}^{2n} \mathcal{V}^i(X)$  has an isolated point, then  $\mathrm{alb} : X \rightarrow \mathrm{Alb}(X)$  is a dominant map. Furthermore, we showed in [LMW18b, Corollary 7.6] that if the Albanese map of  $X$  is proper and semi-small, then in order to conclude that  $\mathrm{alb}$  is an isomorphism it is sufficient (and necessary) to ask that  $\mathcal{V}^n(X)$  consists of finitely many points.

Before stating the next and final question, we recall the following:

**Definition 4.12.** A proper morphism of complex spaces  $f : X \rightarrow Y$  is called a *homotopy fiber bundle* if  $Y$  has an open cover  $Y = \bigcup_j U_j$  such that for every  $j$  and for every  $y \in U_j$  the inclusion

$$f^{-1}(y) \rightarrow f^{-1}(U_j)$$

is a homotopy equivalence.

The following is a simplified version of a question of Bobadilla and Kollár [BK12, Question 4.2 and Conjecture 3]:

**Question 4.13.** Let  $X$  be a smooth complex projective variety. Assume that the universal free abelian cover of  $X$  is homotopy equivalent to a finite CW complex. Does this imply that  $\mathrm{alb} : X \rightarrow \mathrm{Alb}(X)$  is a homotopy fiber bundle, or even a differentiable fiber bundle?

While this question is still open in general, Corollary 4.10 can be viewed as a partial answer.
